

Linear expression such as  $2x + 1$  have no smallest or greatest values. Substituting greater and greater positive numbers (as  $x$ ) into  $2x + 1$  produces greater and greater values. Similarly, substituting large negative numbers (as  $x$ ) into  $2x + 1$  produces negative values with increasing absolute value.

Quadratic expressions are fundamentally different, as no square of any real number is negative. Consequently, most quadratic expressions have a smallest possible value: zero.

**Example 1.** What is the smallest value of each of the following quadratic expressions?

a)  $x^2$       b)  $(x - 4)^2$       c)  $(2x + 1)^2$       d)  $(x + 7)^2$

- Solution: a) No real number can have a negative square. Consequently, if  $x^2$  could take the value zero, that would be the smallest value. That is possible, when we square  $x = 0$ . Thus, the lowest value of  $x^2$  is zero, when  $x$  is zero.
- b) Recall that  $(x - 4)^2$  is a complete square; a difference squared. No matter what the value of  $x$  is,  $x - 4$  is a real number and so it can NOT have a negative square. Consequently, if  $(x - 4)^2$  could take the value zero, that would be the smallest value. That is possible, but only when we square zero. Thus, the lowest value of  $(x - 4)^2$  is zero, when  $x - 4$  is zero, that is, when  $x = 4$ . (Just solve the linear equation  $x - 4 = 0$ ). In short: the lowest value of  $(x - 4)^2$  is zero, when  $x = 4$ .
- c) Recall that  $(2x + 1)^2$  is a square, thus no value for  $x$  will ever result in a negative value. Consequently, if  $(2x + 1)^2$  could take the value zero, that would be the smallest value. That is possible, but only when we square zero. Thus, the lowest value of  $(2x + 1)^2$  is zero, when  $2x + 1 = 0$ . We solve the linear equation  $2x + 1 = 0$  for  $x$  and obtain  $x = -\frac{1}{2}$ . So, the lowest value of  $(2x + 1)^2$  is zero, when  $x = -\frac{1}{2}$ .
- d) Since  $(x + 7)^2$  is a square, no value for  $x$  will ever result in a negative value. Consequently, if  $(x + 7)^2$  could take the value zero, that would be the smallest value. That is possible, but only when we square zero. Thus, the lowest value of  $(x + 7)^2$  is zero, when  $x + 7 = 0$ . We solve the linear equation  $x + 7 = 0$  for  $x$  and obtain  $x = -7$ . So, the lowest value of  $(x + 7)^2$  is zero, when  $x = -7$ .

**Example 2.** Find the smallest value of each of the following quadratic expressions.

a)  $x^2 + 25$       b)  $(x - 4)^2 - 1$       c)  $(2x + 1)^2 + 12$       d)  $(x + 7)^2 - 100$

Solution: First imagine a room where some people gathered. Everyone empties their vallets and pockets and count all their cash and then compare. As it turns out, Mr. X has the least amount of money on them, only \$1.50. Then another hour later, everyone in the room receives \$20. Who has the least amount of money now? The answer is clearly Mr. X, this time with \$21.50.

- a) Consider the expression  $x^2 + 25$ . Recall that the lowest value of  $x^2$  is zero, when  $x$  is zero. Then the lowest value of  $x^2 + 25$  is 25, when  $x$  is zero. (Imagine that the 'poorest' person in the room was Ms. Y, with no money on her. If then everyone in the room receives \$25, she would still be the one with the smallest amount of money, exactly \$20.)
- b) Consider now the expression  $(x - 4)^2 - 1$ . The lowest value of  $(x - 4)^2$  is zero, when  $x = 4$ . Then the lowest value of  $(x - 4)^2 - 1$  is  $-1$ , when  $x = 4$ .

- c) Consider now the expression  $(2x + 1)^2 + 12$ . Because it is a square, the lowest value of  $(2x + 1)^2$  is zero, when  $x = -\frac{1}{2}$ . Then the lowest value of  $(2x + 1)^2 + 12$  is 12, when  $x = -\frac{1}{2}$ .
- d) Consider now the expression  $(x + 7)^2 - 100$ . Because it is a square, the lowest value of  $(x + 7)^2$  is zero, when  $x = -7$ . Then the lowest value of  $(x + 7)^2 - 100$  is  $-100$ , when  $x = -7$ .

**Example 3.** Find the smallest value of each of the following quadratic expressions.

a)  $x^2 + 2x - 5$     b)  $x^2 - 8x + 15$     c)  $x^2 - 12x$     d)  $x^2 - 100$

Solution: a) We will apply the same ideas, but first we need to transform this expression into a more suitable form. For that, we simply complete the square. Half of the linear coefficient is 1, so our suitable complete square is  $(x + 1)^2$ .

$$\begin{aligned} E &= x^2 + 2x - 5 && \text{helper line: } (x + 1)^2 = x^2 + 2x + 1 \\ &= \underbrace{x^2 + 2x + 1}_{(x+1)^2} - 1 - 5 && \text{so we smuggle in 1} \\ &= (x + 1)^2 - 6 \end{aligned}$$

This form of a quadratic expression is often called **the standard form**. Once we brought the expression to the standard form, we can easily determine the smallest value. The smallest value of  $(x + 1)^2 - 6$  is  $-6$ , when  $x = -1$ .

- b) Consider the expression  $x^2 - 8x + 15$ . We complete the square to bring the expression to its standard form.

$$\begin{aligned} E &= x^2 - 8x + 15 && \text{helper line: } (x - 4)^2 = x^2 - 8x + 16 \\ &= \underbrace{x^2 - 8x + 16}_{(x-4)^2} - 16 + 15 && \text{so we smuggle in 16} \\ &= (x - 4)^2 - 1 \end{aligned}$$

Once we brought the expression to the standard form, we can easily determine the smallest value. The smallest value of  $(x - 4)^2 - 1$  is  $-1$ , when  $x = 4$ .

- c) Consider the expression  $x^2 - 12x$ . We complete the square to bring the expression to its standard form.

$$\begin{aligned} E &= x^2 - 12x && \text{helper line: } (x - 6)^2 = x^2 - 12x + 36 \\ &= \underbrace{x^2 - 12x + 36}_{(x-6)^2} - 36 && \text{so we smuggle in 36} \\ &= (x - 6)^2 - 36 \end{aligned}$$

The smallest value of  $x^2 - 12x$  is  $-36$ , when  $x = 6$ .

- d) Consider the expression  $x^2 - 100$ . We do not complete the square as the expression is already in its standard form. If it helps, we can think of  $x^2 - 100$  as  $(x - 0)^2 - 100$ . Either way, the smallest value of  $x^2 - 100$  is  $-100$ , when  $x = 0$ .

Completing the square is not just a factoring technique. It is really our only way (at this point) to determine the smallest value that the expression takes. Completing the square is a way to understand quadratic expressions.

## Practice Problems

Find the smallest value of each of the following expressions.

1.  $x^2 - 4x + 7$

3.  $x^2 - 2x$

5.  $x^2 - 100x + 60$

7.  $x^2 - 16$

9.  $x^2 - 4x + 4$

2.  $x^2 + 10x + 14$

4.  $x^2 + 6x + 42$

6.  $x^2 + 8x + 20$

8.  $x^2 - 16x + 4$

10.  $x^2 + 18x + 81$

## Enrichment

- Not all squares produce zero as their smallest value. Consider the expression  $(x^2 + 3)^2$ . What is the smallest value of this expression? How about  $(x^2 + 3)^2 - 1$ ? And  $x^4 + 10x^2 + 14$ ?
- Until now, the quadratic expressions we saw all had a leading coefficient of 1. How is our argument modified with different leading coefficients? Discuss the smallest value of each of the given expressions.

a)  $3(x - 5)^2 + 8$

b)  $-2(x + 1)^2 - 49$

c)  $5((x + 4)^2 - 25)$

## Answers

## Practice Problems

1. 3   2. -11   3. -1   4. 33   5. -40   6. 4   7. -16   8. -60   9. 0   10. 0
